A household survey of the cost of illness due to air pollution in Beijing, China

Popp Jin*, Y., M. Quan*, C. Ravetti[†], Z. Shiqiu*, T. Swanson †

Abstract

This paper examines with a case study of Beijing, China, the health benefits that could be reaped from urban air quality improvements. The study implements a household survey to collect information about the yearly medical expenditures and lost days of work, to estimates the total costs of illness (COI) borne by a typical individual due to airborne diseases. The results of this survey provide a lower bound for the health costs borne by the urban population of Beijing due to air pollution. We find that the average individual COI in our sample is more than 3000 yuan per year, corresponding to almost one month of the average wage (slightly more than 500 US\$ per year). This is quite sizeable, considering that it represents just the minimum benchmark for the damages caused by pollution to health. This result indicates that Beijing could benefit quite substantially from reducing air pollution in terms of health costs: if it could completely eliminate pollution, the savings in terms of COI would range in an order of magnitude of 21 million yuan per year only from hospitalized cases.

The research leading to these results has received funding from the European Union's Seventh Framework Programme (FP7/2007-2013) under the grant agreement n° 266992 (GLOBAL IQ).

Introduction

In developing countries, global environmental problems such as climate change might be perceived as second order concerns, compared to more urgent developmental needs. Even local problems, such as urban air pollution, are rarely considered to be among the top priorities by governments in such countries, despite potentially large health costs imposed upon the population. A typical example is the case of China, a country that suffers from air pollution to a particularly large extent: according to the Asian Development Bank, 7 out of 10 of the most polluted cities in the world are in China, and 70% of the total urban population (more than 360 million) live in areas with hazardous air quality (ADB 2007). In China local environmental problems are imposing substantial costs on that society.

Moreover, these local environmental problems can be linked to global issues as well. Many of the same production processes and congestion problems result in both local and global pollutants. It could be therefore argued, in line with the literature on ancillary benefits of climate change mitigation policies (Ravetti et al. 2014), that China could benefit from lowering these emissions, both for the health of its current population and for the welfare of future generations everywhere.

This argument requires some estimates of the local values that are to be obtained from generating cleaner air. One of the main impacts of poor air quality is its effects on health, both acute and chronic. Many respiratory complaints and illnesses can be linked to the pollutants flowing into local air supplies. Efforts to reduce these health effects may target the same production processes that generate global problems as well as these local problems. To persuade authorities to take these environmental problems seriously, some measure of the local impacts may be necessary.

This study pursued this objective by means of attempts to quantify the health impacts of local air pollutants in Beijing. We conducted a survey, consisting of a computer-based questionnaire provided to approximately one thousand five hundred residents of the city, in which individuals were questioned about the incidence of respiratory illness, and the costs of these illnesses (both in terms of lost days and also in terms of

self-protective measures) across these households. This survey provides a "cost of illness" (COI) approach to measuring the real impacts of air quality in Beijing (El Fadel and Massoud 2000). This approach is of course subject to caveats regarding the respondents' abilities to recollect or respond accurately for the surveyor, and in terms of the types of costs considered -. These benefits from management of air pollution problems are demonstrated here to be significant and real.

Household Survey

The first survey reported here was conducted jointly by Peking University and IHEID in order to measure the cost of respiratory illnesses potentially linked to air quality problems in Beijing. For purposes of this study, we focused on securing data on actual health problems in the city, and the costs flowing from these health problems (in terms of averting behaviour and avoided work).

One of the key difficulties in estimating the cost of illness in China is data limitation: hospital data are very imprecise, and household surveys are rarely representative in terms of sampling, as they are usually based on street interviews and so-called "typical sampling". This survey tries to overcome these problems by collecting health characteristics from a sample that was carefully designed to be representative of the whole of Beijing. Obtaining authorization for collecting such data is quite complex in Beijing, but the resulting dataset has many important characteristics for analysis. First of all, it can ensure that the sample is representative of the three districts sampled (unbiased) and, as long as other districts in Beijing are not too different, results for this sample could be extended to the entire urban area (external validity). Moreover, collecting data door-to door rather than interviewing in the streets allows for longer and more detailed questionnaires. Therefore, even without hospital data, we can approximately apply the estimated COI the city level, to get a broad sense of the magnitude of gains that a reduction in air pollution would imply for individual costs of airborne disease.

1 - Survey and Data

1.1 Survey period

The survey interviews were conducted under the supervision of the College of Environmental Science and Engineering of Peking University (PKU). Pilot studies and extensive training for interviewers were done in the initial month of the study in order to ensure the clarity and effectiveness of the survey.

1.2. Questionnaire

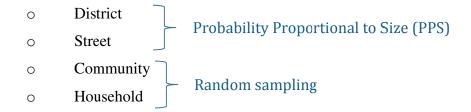

The household survey consisted of different sections, comprising:

- Personal characteristics: age, education, income and financial information, smoking status, extended family support, location and past migration, division of tasks in the house.
- Health and airborne diseases: symptoms, acute, chronic, other diseases, selfrated health, insurance expenditure, direct and indirect cost of illness.
- Exposure to air pollution: transportation, time of commuting, daily time outdoors.
- Information on pollution: how the household accessed information on daily pollution levels.
- Averting behaviours in normal or extreme times, and use of air purifier.

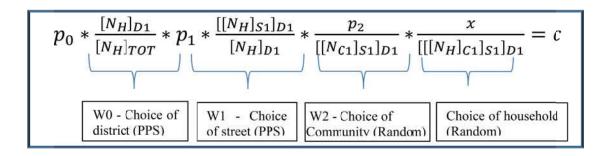

In addition, at the end of the interview the investigator annotated the length of the interview, how willing to respond was the interviewed person and whether anyone disturbed the respondent. Interviews were registered and a random sample of registration was checked for any systematic mistakes by an interviewer.

1.3 Sampling

We obtained a sample of 578 respondents (1672 individuals) in three districts of Beijing, Haidian, Dongcheng and Chaoyang applying the following sampling procedure:

We wanted to ensure that every household in Beijing had the same chances of being chosen for our survey, a priori. Given the different steps of selection, the complete probability of a household being interviewed was:

For any given person, this was the product of the probability that *his/her* district was chosen, then *his* street, then *his* community, and finally *his* household, all together. It assumes that the choice of District and Street was done based on its population, i.e. giving larger chances to bigger units. This is done by Probability Proportional to Size (PPS) selection.

 N_H is the number of households, the subscript indicates where.

 $[N_H]_{TOT}$ is the total number of households in the Beijing population, 220.5

 $[N_H]_{D1}$ is the total number of households in District 1

 $[[N_H]_{S1}]_{D1}$ is the total number of households in Street 1, District 1

 $[[[N_H]_{C1}]_{S1}]_{D1}$ is the total number of households in Community 1, Street 1, District 1

 N_H chosen in C1 is the number of chosen households in Community 1, Street 1, District 1. It is the key variable we can change to make probabilities match, which we can call X.

 p_0 is just 3, the number of districts we are choosing out of the total ones

 p_1 is the number of streets we are selecting in a district, given total number of streets in that district (e.g. in DC is 2)

 p_2 is the number of selected communities chosen in a given street for a given districts. Probably will be given to us by the Street leader.

c is the final probability, which we want to be constant for all households.

The above equation illustrates the probability for a household in District 1, in Street 1 and in Community 1 to be selected. We have many of such equations, indicating the probability of households in all other districts, streets and households being selected.

In order to guarantee that this probability is constant across all households (c is the same for all equations), we set X as an arbitrary but reasonable number for the first of these equations, then we solve in all others for X so to guarantee that the equality always holds. In this way, every household chosen has the same probability of selection, c (and so would have had any other household in Beijing, if it had undergone the same selection process):

$$x = c * [[[N_H]_{C1}]_{S1}]_{D1} * \frac{1}{[p_0 * \frac{[N_H]_{D1}}{[N_H]_{TOT}} * p_1 * \frac{[[N_H]_{S1}]_{D1}}{[N_H]_{D1}} * \frac{p_2}{[[N_{C1}]_{S1}]_{D1}}]}$$

The resulting sample is structured as follows:

District	Total agents	Total households	Community	Individuals	Households
			fuyi	44	16
			dongnan	61	21
			hualian	40	16
Haidian	628	215	hejianlou	63	25
пашап	020		zefengyuan	72	21
			huangzhuang	45	18
			taiyangyuan	78	25
			dongyingfang	88	27

			xiaonanzhuang	68	23
			daoxiangyuannan	63	22
			jingtai	46	16
			taoyanglu	105	32
Dongcheng	455	156	xigexinli	78	30
			jinbaojiebei	117	40
		185	zhaojialou	103	36
			yuhuili	36	13
	500		xibahexili	57	22
			guangximenbeili	51	20
			balizhuangnanli	48	18
Chaoyang			chenguangjiayuan	58	23
Chabyang			shilipunanli	26	10
			liulitunbeili	55	19
			xibahenanli	46	17
			huizhongli2	81	27
			huizhongbeili1	54	19
Total	1583	556		1583	556

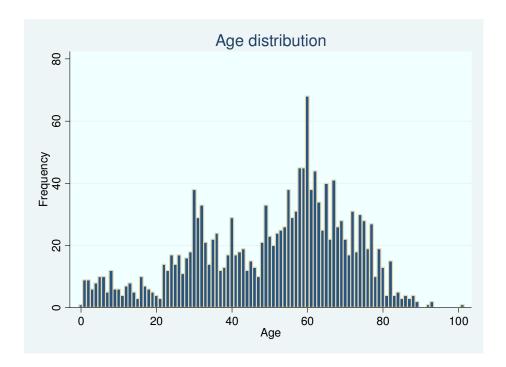

1.4. Stylized facts

In terms of age, gender, education and income characteristics of our surveyed individuals, these reflect quite accurately the characteristics of the overall population, as described in the Beijing Statistics Bureau. In some cases a direct comparison is possible with data from the Bureau (see gender) and the survey results in line with official figures.

1.4.1 Age, gender, education

District	Average age
Dongcheng	50.9
Haidian	50.8
Chaoyang	49.8

The age distribution is shown below: the distribution is slightly skewed to the right, indicating that older respondents were more likely to be at home to respond to the interviews. However, since this problem of age bias is well known in door-to-door interviews, the time and days of visits were greatly varied to ensure that different people could respond to the questionnaire.

Averages by district and by gender group are well representative of the districts and are very close to the official statistics of the National Census.

Age by gender group						
	Survey	6th national census				
	Female (%)	Male (%)	Female (%)	Male (%)		
Dongcheng	52.7	47.4	50.6	49.4		
Haidian	51.1	48.9	48.3	51.7		
Chaoyang	52.4	47.6	48.5	51.5		
Average	51.8	48.2	-	-		

In terms of education, Beijing has relatively high levels of literacy:

District	Average education ²
Dongcheng	3.5
Haidian	3.7
Chaoyang	3.6
Average	3.6 (between middle school and high school/technical school)

Given the characteristics of the population in these districts, it is reasonable that the average education level in Haidian is higher than in the two other districts. However these values are not directly comparable with Statistical Yearbook averages, since their definition differs from the one used in the survey.

1.4.2 Income and monthly wage

Also household income is comparable to the official statistics, but only for past years. Since we asked for information about income also 2 and 5 years in the past, these are then comparable.

		Survey	Statistical Yearbook			
	Total					
Districts	household 2 years		5 years ago	2 years ago	5 years ago	
	income (year)					
Dongcheng	84'135	91'200	53'878	85'491		
Haidian	147'756	112'246	103'379	109'078		
Chaoyang	117'804	105'368	82'185	93'256	68'701	
Average	119'931	105'673	79'814	95'942		

In our survey, the comparable values are slightly higher, but this is aligned with

² The education levels correspond to: 1. Just basic literacy/kindergarten 2. Primary 3.Middle school 4 High school /Technical school 5 University 6 Master and above (PhD, Postdoc)

the literature that identifies a downward bias in the household income declared in the Census interviews reported in the Statistical yearbook (Bramall 2001).

Net Monthly Wage(yuan/month)						
District	Average	Female	Male			
Dongcheng	3918	4014	3844			
Haidian	5651	4279	6671			
Chaoyang	4899	4095	5504			
Total	4883	4140	5441			

2 - Analysis

2.1 Airborne diseases

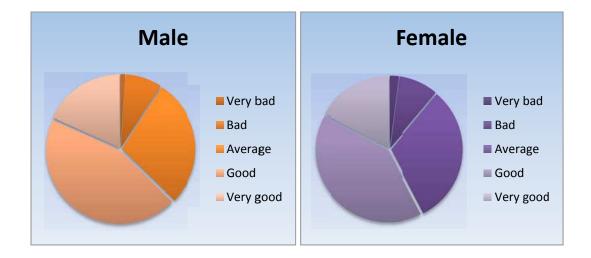

The survey asks a detailed set of questions about the health status of the interviewees and their families, especially in relation to airborne illnesses that can be connected to pollution and exposure. Below are summarized some of the characteristics of these variables.

2.1.1 Self-rated health

How do you consider your health compared to the same age group and same gender?

Self-rated health	Total
1 - very good	18 %
2 – good	42 %
3 – average	30 %
4 – bad	9 %
5 - very bad	2%
Average rating	2.3

By gender, there are no striking differences in health perception:

2.2.2 Symptoms

We proposed a list3 of respiratory symptoms that the literature connects with air pollution and ask respondents to indicate if they suffer from any of these, and if so when.

Suffering from air-pollution symptoms	Frequency	Female	Male	Total months with symptom episodes in a year (average)
No	46 %	43%	49%	1.9
Yes but they are not so bad, I can go on with my daily life	42 %	44%	40%	7% of sample has symptoms during the entire year.
Yes and they are bad, they affect what things I can do in my daily life, I have to take some medicines	11 %	11%	10%	
Very bad, I often take medicines, sometimes I have to stay in bed, they hurt a lot.	1 %	1%	1%	

_

³ Symptoms considered are: Eye/nose/throat irritation; Runny nose/Cold; Flu/Fever; Skin infection/ rash; Asthma attacks; Shortness of breath; Respiration allergy to dust; Dry scratchy throat; Chest pain; Cough with phlegm; Dry cough; Drowsiness; Headache; Whistling and wheezing in the chest.

2.2.3 Acute, chronic and other disease

For chronic diseases, 90% of cases are diagnosed by doctor. On average, in our sample individuals have been suffering from the chronic disease for previous 14 years.

These chronic airborne diseases	Compared to 2 years ago	Compared to 5 years ago
Didn't have them	7 %	20 %
It improved	17 %	13 %
It got worse	15 %	16 %
Stayed the same	60 %	51 %

For acute episodes of airborne illnesses, only 55% were diagnosed by a doctor. In fact, when asked what they do when in pain, almost half of our sample declared that they only adopted self-care measures.

Acute airborne illnesses episodes: how many months	Percentage
0	70 %
1	12 %
2	11 %
> 2	6 %
All year	1 %

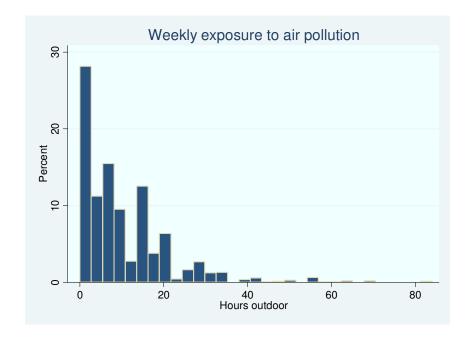

2.2 Exposure (time outdoor)

The survey collects information about weekly exposure to air pollution, in the form of time spent outdoor for leisure or for work, during weekdays and weekends, during two different parts of the year, hotter and colder months. This information is then aggregated to obtain weekly exposure, by averaging these

values over the whole year and then summing for weekly exposure the daily hours out (multiplying by 5 the weekday exposure and by two the weekend one).

Summer (April -Oct)			Winter (Nov-March)				
Weekday Weekend		Weekday		Week	end		
Leisure	Work	Leisure	Work	Leisure	Work	Leisure	Work
1.5 hours	0.1	1.7	0.1	1.2	0.1	1.3	0.1
Average (weekly)	10 hours outdoor a week						

But with great heterogeneity, as illustrated in the histogram below.

3 -Results

3.1 Correlations: health expenditure and illnesses

Instead of simply correlating the yearly cost of illness with pollution, which is invariant for individuals, we look at the correlation to individual exposure. Cost

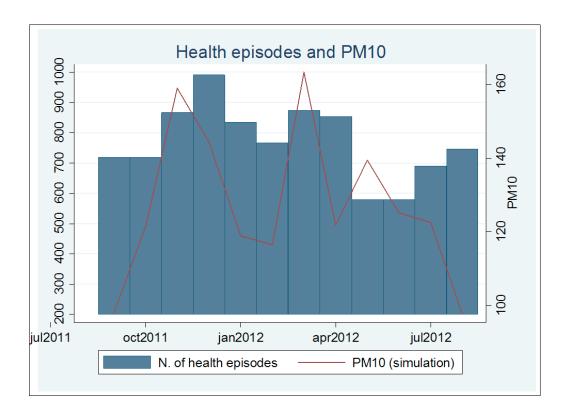

of illness does not have a time dimension, as we only have the total spending for the whole year, direct and indirect costs, see Paragraph 3.3, while for acute, chronic and symptoms we ask to recall the monthly variation of illness episodes.

	Exposure	COI	Acute	Chronic	Symptoms	Self-rated
COI	0.0761	1.0000				
	0.0086					
Acute	0.0124	0.0125	1.0000			
	0.6297	0.6581				
Chronic	0.1186	0.3093	0.0054	1.0000		
	0.0000	0.0000	0.8280			
	0.0=00	0.404=	0.400=	0.0006	4.0000	
Symptoms	0.0539	0.1247	0.1297	0.2036	1.0000	
	0.0355	0.0000	0.0000	0.0000		
Self-rated	-0.0061	0.3009	0.0108	0.3519	0.1686	1.0000
	0.8123	0.0000	0.6633	0.0000	0.0000	

Highlighted in bold are the significant correlations. Acute diseases are somewhat different: they do not significantly correlate with hours of exposure, or with cost of illness.

3.2 Exposure and illness episodes

Using air pollution data on particulate matter from Beijing monitors and the monthly variation of illness episodes, we can see that the total airborne diseases in our sample tent to move together with the pollution levels. We are not trying to estimate here dose-response functions, since there is a much more accurate epidemiological literature doing it, but at least we can observe that air pollution peaks tend to come together with more episodes of airborne disease.

3.3 Cost of Illness (COI)

The COI represents a lower bound on how much people would gain from reduced airborne diseases: it only takes into account direct costs, and gives no value to pain, inconvenience and non-monetary damages caused by the illness. It is however a good benchmark to estimate the minimum level of benefits that the population would enjoy from reduced air pollution.

3.2.1 Direct and indirect costs

In our sample, airborne illnesses appear to be a substantial component of total medical expenditure, making up for more than half of total direct costs of sickness over the year. This might be overestimated, given that our survey gave much more importance to airborne diseases than to all sickness, but it gives an indication that airborne diseases are not an irrelevant component of the medical expenditure of a Beijing resident. However people tended not to take days off because of these airborne diseases, nor remain inactive (more than 90% of respondents indicated zero work days lost because of airborne diseases).

	Direct cost of airborne illness	Days of work lost	Paid sick leave	Days of inactivity
Average (only airborne diseases)	2514 yuan	1.4	0.5	9
Average (including other illnesses) ⁴	5184 yuan	18	13	53

We can calculate the indirect costs of illness as foregone wage, which was not earned due to the illness nor compensated as sick leave. From this, we get the total cost of illness experienced by the individual.

	Indirect cost of illness = wage* (days lost-sick leave days)	Total cost of illness
Average (only airborne diseases)	812 yuan	3326 yuan
Average (including other illnesses)	305 yuan	5489 yuan

Again, results are much more accurate for airborne diseases than for total illnesses. It is in fact somewhat puzzling that, even if more days are lost for total illnesses than for airborne ones, the foregone wage should be smaller for the former than for the latter (around 800 versus 300 yuan). This could be due to the very specific sample of people who declared also other illnesses beyond airborne ones, probably those who suffer from some other very invalidating disease which correlates with a much smaller wage anyways.

Nonetheless, looking at these results, we can see that airborne diseases are quite costly on average for the Beijing population: more than 3000 yuan per year, corresponding to almost one month of the average wage (a bit more than 500 US \$ per year).

⁴ Note that we have a much smaller sample of respondents for all other illnesses: for the lost days of work, we have only 86 responses. This might be due to the fact that our survey did not focus on the overall health costs for an individual, but rather on airborne diseases.

3.2.2 Preventive medical consultations and insurance

Furthermore, we asked how many preventive health checks they took in the previous year and how much they had to individually pay for them (i.e. not covered by the insurance, employer, etc.).

Number of preventive medical checks	Frequency	Expenditure	Yuan
0	27 %	Average	102
1	70%	Min	0
>1	3%	Max	15 000

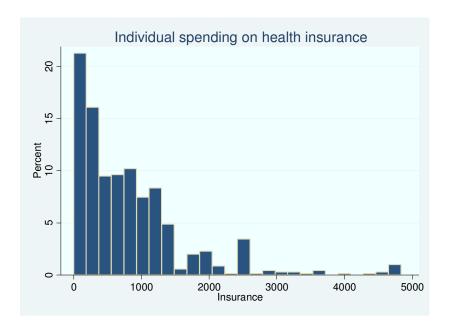

For insurance, the respondents used several different strategies of coverage:

Insurance type	Frequency
No insurance	4 %
Urban employee medical insurance	75%
Urban resident medical insurance	12%
New cooperative medical insurance	0.4%
Other social medial insurance	1 %
Commercial medical insurance	1%
More than one insurance	2.6%
Missing	4%

Average individual spending on insurance is 1063 yuan per year, with few outliers spending much more (up to a maximum of 48 000 yuan) and the majority actually spending very little and relying on what is covered by the government or their employer (see histogram below⁵).

_

⁵ For graphical purposes, the 13 largest expenditure, above 5 000 yuan per year are omitted.

3.2.3 COI and air pollution

An important related policy question is how much a decrease in pollution could reduce this health expenditure. This cannot be answered directly using our survey data, but dose-response functions from the existing literature can be applied in order to understand broadly the order of magnitude of the benefits of pollution reduction. Since our sample was designed to be representative of the Beijing population, COI should as well loosely represent the typical cost faced by an urban resident of the capital,⁶ composed of circa 20 million people.

The epidemiological literature produced a number of estimates for China, related mostly to hospital admission caused by air pollutants, both for mortality and morbidity - for instance Aunan and Pan (2004) finds that the hospital admissions related to respiratory diseases attributable to changes in particulate matter (PM10) had a coefficient of 0.12%. Given that we have a no hospital admission data, we use the factors of change imputed to PM10 in causing acute airborne episodes.

In our sample, over the year there were 1065 acute episodes, of which 544 were cured by a doctor or a nurse in a clinic or a hospital. We can roughly extrapolate these results from our sample to the whole Beijing population, knowing that the

_

⁶ In order to apply the results to the entire country, more complex benefit-transfer methods should be implemented, adjusting at least for different levels of income in other cities or, even more importantly, in rural areas. We leave this for further research.

results will be far from accurate: if the proportions in the total Beijing population are similar to those in our sample, there would be around 13 million episodes of acute airborne disease last year, out of which 6 million would lead to a hospital visit. Therefore a 10 micrograms decrease in PM10, according to the values of the epidemiological literature, would translate into a fall of around 7000 cases of hospitalized acute airborne episodes, or more than 15'000 cases of airborne illnesses, if the coefficient was still valid not only for hospital admissions but for all disease episodes (probably it would be underestimated then). These are very imprecise estimates, but they indicate what order of improvement could be expected from reducing air pollution.

To calculate the monetary value of such a reduction in illness episodes, further assumptions are needed. If we apply the calculated COI of 3326 yuan to every episode, since a person has on average one acute episode per year, we find that the individual saving for the Beijing population from reducing air pollution ranges around 21 million yuan only from hospitalized cases, and more than double for all cases. These are only indicative values, which give very approximate values for the costs of illness to urban residents, however they already provide a general sense of the magnitude of benefits that could be reaped by a single city, should it reduce its pollution emissions.

4 - Conclusion

The results of this survey provide the lowest possible bound for the health costs to the urban population of Beijing of air pollution. Simply accounting for medical expenditures and foregone wage due to airborne diseases, we see that the average cost of illness is sizeable at the individual level, and becomes very large when aggregated and scaled up at the city level. These results exist, even without taking into consideration public costs, e.g. costs to the health system (hospital beds, medicines covered by the state, public insurance, etc.), and ignoring all intangible private costs (discomfort, pain, other costs not stated in the survey).

⁷ With a population of 20 million people, if the relationship is stable we have that: 1639:20 000 000=1065:Y1 and 1639:20 000 000=544:Y2. Y1 solves to 12 995 729 (episodes of acute airborne diseases). Y2 solves to 6 638 194 (episodes of acute diseases that require to go to the hospital)

E. Averting behaviour

Reason	Example
0 Misunderstanding	Although the air is haze, the air quality is not bad Haze air doesn't hurt health Should exercise more to improve their physique in haze air. Think this behavior doesn't help to avert effectively
1 Low elasticity of behaviour	Difficult to change long-standing habit Hope to change, but cannot to The time outdoor is already very little, cannot reduce more Uncomfortable to wear a mask
2 Good health	Health is good, so don't worry about the haze air
3 Not applicable	During that time no plan for go out for exercise or leisure Already the best way (e.g. by car or taxi)
4 Other	

Under extreme circumstances (ask only if they noticed them, see question D3 D4) Assume those who do not know will behave same as in normal times.

	Did you ever do t extreme air poll	Did you ever do the following during the extreme air pollution days this year.	Did you ever do the following during the E2.1 (all no for E1 E2) E3. Did you change E3.1 If yes, specify below from E3.2 If E4. Did you wear E4.1 if no, the not search of the two (see table 1 transportation).	E3.
